

It's a wild, *wild* drink.

It all starts with the canopy

Tall trees protect the coffee trees from the wind and provide the necessary shade, neither too much nor too little. They are also an excellent natural compost for the soil.

A preserved natural ecosystem

Here shade trees are king and preserve the functioning of a fragile ecosystem. Thanks to their presence, the forest and its inhabitants are protected.

A bountiful forest

The wealth of the ecosystem allows producers to diversify their incomes by producing honey, spices or firewood.

A slow method

This biodiversity reservoir allows coffee trees to grow slowly in optimal, and almost primitive conditions. Slow maturation is essential to reveal complex aromas in the cup.

Organic by nature

No need for fertilizers or pesticides here. The ecosystem of such forests naturally nourishes and regenerates a rich and fertile soil.

Value the work of the producers

The quality of the coffees, which can be traced all the way to the plot, enables higher incomes for the producers who can then invest in their farms.
